

Metal Industry Indicators

Indicators of Domestic Primary Metals, Steel, Aluminum, and Copper Activity

May 2004

The primary metals leading index pulled back in April after rising for six straight months, but this does not indicate that the current expansion in industry activity is likely to end in the near future. The leading index of metal prices dropped sharply in March, which would normally suggest that metal prices could fall. However, tight supplies and continued global and domestic demand for metals could keep prices modestly high for the near term.

The primary aluminum and the aluminum mill products indexes are suspended because of discontinued availability of industry-specific historical data. The USGS will continue to calculate the steel and copper composite indexes.

The **primary metals leading index** slipped 0.3% in April, decreasing to 142.6 from a revised 143.0 in March, and its 6-month smoothed growth rate fell to 10.6% from a revised 13.2%. The 6-month smoothed growth rate is a compound annual rate that measures the near-term trend. Normally, a growth rate above +1.0% signals an upward trend for future growth in metals activity, while a growth rate below –1.0% indicates a downward trend. For an explanation of these indexes and a definition of the primary metals industry, [see page 10](#).

The JOC-ECRI metals price index growth rate, which declined for the first month in nearly a year, made the largest negative contribution to the leading index. The decrease in the Institute for Supply Management's PMI was so slight that its contribution rounded to zero. In contrast, the combined S&P stock price indexes for construction and farm machinery companies and for industrial machinery companies, rebounded to a new high in April and made a large positive contribution to the leading index. The length of the average workweek in primary metals establishments also helped to buoy the leading index. These positive contributions, however, were not large enough to offset the deep decline in the JOC metals price growth rate. Because only four of the eight index components were available, April's primary metals leading index should be considered preliminary.

Although the leading index growth rate decreased in April, the expansion in the primary metals industry is still underway. The U.S. and global economies are still positioned for further growth and demand for metals remains moderately high.

The **steel leading index** increased 1.1% in March, the latest month for which it is available, rising to 114.8 from 113.5 in February. Its growth rate moved up to 4.9% from 3.5% in February. Only one of its nine components, average weekly hours in iron and steel mills, decreased in March. New orders at iron and steel mills made a large positive contribution to the overall increase in the leading index. The index's growth rate suggests modest activity growth in the domestic steel industry in the months ahead.

The **copper leading index** gained 1.2% in March after increasing that same amount in February, moving to 128.0 from a revised 126.5 in February, and its 6-month smoothed growth rate increased to 11.9% from a revised 10.9% in February. Five of the index's six components increased in March, with only the yield spread between the Federal funds rate and the 10-year Treasury bill declining. The other indicators continued the strong performance of the past year. The leading index growth rate has been indicating a pickup in U.S. copper industry activity since last summer; the coincident index growth rate is now reflecting that signal.

Tight Metals Supplies Keep Prices High

The **metals price leading index** decreased 1.6% in March, the latest month for which it is available, falling to 113.4 from a revised 115.2 in February, and its 6-month smoothed growth rate settled at zero from a revised 3.8% in February. Two of the three available leading index components decreased in March.

The growth rate of the index measuring the trade-weighted average exchange value of other major currencies against the U.S. dollar made a -1.4-percentage-point contribution. The yield spread between the U.S. 10-year Treasury Note and the federal funds rate decreased, making a -0.3-percentage-point contribution. However, an increase in the growth rate of the inflation-adjusted value of new orders for U.S. nonferrous metal products contributed only 0.1 percentage point to the net decline in the leading index.

The fourth index component, the growth rate of the Economic Cycle Research Institute's (ECRI) 18-Country Long Leading Index decreased in February, the latest month for which it is available. This component has generally increased over the past year and is still in the range that supports continued growth in global economies. The ECRI 18-Country Long Leading Index

signals changes in the growth of economic activity in major industrialized countries about 5 months in advance.

The growth rate of the inflation-adjusted value of inventories of U.S. nonferrous metal products, which is an indicator of metals supply, continues to fall and rests at -8.7% for the two most recent months. This indicator tends to move inversely with the price of metals. Tight supplies and relatively high demand for metals could keep metals price growth at a modest pace in the near future.

The business cycle and inventories are only two factors in metals price determination. Other factors that affect prices include changes in metals production, speculation, strategic stockpiling, foreign exchange rates, geopolitical instability, and production costs.

Table 1.
Leading Index of Metal Prices and Growth Rates of the Nonferrous Metals Price Index, Inventories of Nonferrous Metal Products, and Selected Metal Prices

NA: Not available r: Revised						
Note:	The components of the Leading Index of Metal Prices are the spread between the U.S. 10-year Treasury Note and the federal funds rate, and the 6-month smoothed growth rates of the deflated value of new orders for nonferrous metal products, the Economic Cycle Research Institute's 18-Country Long Leading Index, and the reciprocal of the trade-weighted average exchange value of the U.S. dollar against other major currencies. The Metal Industry Indicators (MII) Nonferrous Metals Price Index measures changes in end-of-the-month prices for primary aluminum, copper, lead, and zinc traded on the London Metal Exchange (LME). The steel scrap price used is the price of No. 1 heavy melting. Inventories consist of the deflated value of finished goods, work in progress, and raw materials for U.S.-produced nonferrous metal products (NAICS 3313, 3314, & 335929). Six-month smoothed growth rates are based on the ratio of the current month's index or price to its average over the preceding 12 months, expressed at a compound annual rate.

NA: Not available **r:** Revised

Note: A component's contribution, shown in Tables 3, 5, 7, and 9, measures its effect, in percentage points, on the percent change in the index. Each month, the sum of the contributions plus the trend adjustment equals (except for rounding differences) the index's percent change from the previous month.

CHART 6.
COPPER: LEADING AND COINCIDENT INDEXES, 1982-2004

CHART 7.
COPPER: LEADING AND COINCIDENT GROWTH RATES, 1982-2004

Explanation

Each month, the U.S. Geological Survey tracks the effects of the business cycle on five U.S. metal industries by calculating and publishing composite indexes of leading and coincident indicators. Wesley Mitchell and Arthur Burns originated the cyclical-indicators approach for the economy as a whole at the National Bureau of Economic Research in the mid-1930s. Over subsequent decades this approach was developed and refined, mostly at the National Bureau, under the leadership of Geoffrey H. Moore.¹

A business cycle can briefly be described as growth in the level of economic activity followed by a decline succeeded by further growth. These alternating periods of growth and decline do not occur at regular intervals. Composite indexes, however, can help determine when highs and lows in the cycle might occur. A composite index combines cyclical indicators of diverse economic activity into one index, giving decision makers and economists a single measure of how changes in the business cycle are affecting economic activity.

The indicators in the metal industry leading indexes historically give signals several months in advance of major changes in a coincident index, a measure of current metal industry activity. Indicators that make up the leading indexes are, for the most part, measures of anticipations or new commitments to various economic activities that can affect the metal industries in the months ahead.

Composite coincident indexes for the metal industries consist of indicators for production, shipments, and total employee hours worked. As such, the coincident indexes can be regarded as measures of the economic health of the metal industries.

The metal industry coincident indexes reflect industry activity classified by the U.S. Standard Industrial Classification (SIC) and the North American Industry Classification System (NAICS). Of the five metal industries, primary metals (NAICS 331) is the broadest, containing 25 different metal processing industries. Steel, aluminum, and copper are specific industries within the primary metals group.

The SIC was the main vehicle used by the U.S. Government and others in reporting industry economic statistics throughout most of the last century. Starting with the 1997 U.S. Economic Census, the U.S. Government began using the NAICS, which classifies economic data for industries in Canada, Mexico, and the United States. In general, metal industry indexes starting in 1997 begin to reflect the NAICS classification, while indexes for earlier years follow the SIC. Hence, composite indexes from 1997 forward are not entirely consistent with those of earlier years.

The largest change to primary metals because of the NAICS deals with other communication and energy wire manufacturing (NAICS 335929). Under NAICS, this manufacturing has been removed from primary metals and added to electrical equipment, appliance, and component manufacturing. Because monthly shipments and new orders for this wire are not available, the USGS is estimating their values from 1997 onward and adding them to the appropriate metal industry indicators and indexes to maintain consistency.

¹**Business Cycle Indicators, A monthly report from The Conference Board** (March 1996).

There are other small changes to the primary metals industry because of the switch to the NAICS. Coke oven activity not done by steel mills, for example, is removed and alumina refining, a part of industrial inorganic chemical manufacturing under the SIC, is added. Since the historic trends of the composite indexes are not affected by these small changes, the USGS is not making specific adjustments to the indexes for them for the periods before and after 1997.

The metal industry leading indexes turn before their respective coincident indexes an average of 8 months for primary metals and 7 months for steel and copper. The average lead time for the primary aluminum leading index is 6 to 8 months, and the average lead time for the aluminum mill products leading index is 6 months.

The leading index of metal prices, also published in the *Metal Industry Indicators*, is designed to signal changes in a composite index of prices for primary aluminum, copper, lead, and zinc traded on the London Metal Exchange. On average, this leading index indicates significant changes in price growth about 8 months in advance.

The growth rate used in the *Metal Industry Indicators* is a 6-month smoothed growth rate at a compound annual rate, calculated from a moving average. Moving averages smooth fluctuations in data over time so that trends can be observed. The 6-month smoothed growth rate is based upon the ratio of the latest monthly value to the preceding 12-month moving average.

$$\left[\left(\frac{\text{current value}}{\text{preceding 12-month moving average}} \right)^{\frac{12}{6.5}} - 1.0 \right] * 100$$

Because the interval between midpoints of the current month and the preceding 12 months is 6.5 months, the ratio is raised to the 12/6.5 power to derive a compound annual rate.

The growth rates measure the near-term industry trends. They, along with other information about the metal industries and the world economy, are the main tools used to determine the outlook of the industries. A 6-month smoothed growth rate above +1.0% usually means increasing growth; a rate below -1.0% usually means declining growth.

The next summary is scheduled for release on the World Wide Web at 10:00 a.m. EDT, Friday, June 18. The address for *Metal Industry Indicators* on the World Wide Web is: <http://minerals.usgs.gov/minerals/pubs/mii/>

The *Metal Industry Indicators* is produced at the U.S. Geological Survey by the Minerals Information Team. The report is prepared by Kenneth Beckman (703-648-4916; e-mail: kbeckman@usgs.gov), and Gail James (703-648-4915; e-mail: gjames@usgs.gov). The former Center for International Business Cycle Research, under the direction of Dr. Geoffrey H. Moore, and the former U.S. Bureau of Mines developed the metal industry leading and coincident indexes in the early 1990s. Customers can send mail concerning the *Metal Industry Indicators* to the following address:
